Executive summary

OPESc+ is an observatory of world economic indicators. It collects, harmonises and makes available the series published by the major international statistical institutions, so that analysis carried out within the ministry rests on a common, traceable and up-to-date base.

The tool rests on five principles.

1. No locally produced data. The platform computes and estimates nothing. It passes on what the World Bank, the International Monetary Fund and Harvard University's Growth Lab publish, unaltered.
2. Never offer a filter that leads nowhere. The frequencies offered, the countries listed and the period bounds are those that actually exist in the database for the chosen indicator.
3. A missing value is information. It is never stored as zero, never interpolated, and a series with gaps is drawn as a dashed line.
4. Traceable collection. Every run is logged, and every export carries its sources and retrieval date.
5. Data and interpretation kept apart. The projections offered are mechanical extensions, explicitly presented as such.

What OPESc+ is, and what it is not

OPESc+ is a tool for consulting, comparing and reporting. It is not a macroeconomic model: it simulates no shock, computes no scenario and produces no institutional forecast. The three projection methods it offers are statistical extensions of the observed series, with no policy assumption. For shock simulation and reference projections, the tool is OPESc, which OPESc+ complements.

Chapter 1

General presentation

Purpose

OPESc+ is used to:

- consult economic series for every economy in the world;
- compare several countries or several indicators on one chart;
- read a geographic distribution on a world map;
- extend a series using three documented statistical methods;
- export charts, maps and data for use in a note;
- maintain a base updated automatically from the providers.

Functional architecture

The chain has four stages. Connectors query the providers' public interfaces. The collection engine harmonises country codes, periods and units, then writes to a single database. The interface reads that database and never writes to it. Exports produce standalone files carrying their sources.

This separation has a practical consequence: consulting the platform can never alter the data, and a collection in progress does not prevent consultation.

Scope

Dimension	Value
Active indicators	233
Categories	14
Economies covered	about 217
Regional aggregates and income groups	about 40
Time coverage	1960 to the current year
Connected providers	4

Table 1 – Scope of the database

Further indicators appear in the catalogue without being active: their provider has no connector yet. They are deactivated at load time rather than left visible and silent in the interface.

Sources

Provider	Databases	Access
World Bank	World Development Indicators, International Debt Statistics, governance, poverty, Findex, logistics performance	Public interface
World Bank	Pink Sheet, world commodity prices	Monthly workbook
International Monetary Fund	World Economic Outlook, Fiscal Monitor	SDMX portal

Provider	Databases	Access
Growth Lab, Harvard	Atlas of Economic Complexity	GraphQL interface

Table 2 – Providers and databases used

Ownership and citation

The data remain the property of their producers. Harvard University's Growth Lab, the OECD and the International Monetary Fund explicitly require attribution. Every exported workbook carries a Sources sheet stating, for each indicator, its origin and the retrieval date. Never circulate an extract without that sheet.

Getting started

The banner

The banner stays visible at all times, including when scrolling a long page. It carries the arms of the Republic, the platform name, the language selector and the ministry logo. A discreet strip lists Cameroon's ten main trading partners.

The four tabs

Tab	Use
Home	Overview, database figures, links to reference sites, manual download
Dashboard	Charts and maps, projections, exports
Database	Tabular browsing and spreadsheet download
Data collection	Update log and manual refresh

Table 3 – Purpose of each tab

Switching language

The selector on the right of the banner switches between French and English. Switching reloads the page, which is what allows the entire interface to be translated, including labels built once at start-up. A selection in progress is not preserved across that reload, so switch language before composing a chart.

The translation covers the interface, the labels of the fourteen categories, those of the 233 indicators and their units. Country names are supplied in English by the World Bank.

Downloading the manual

The button is on the Home tab, after Browse the database. A form asks for the language and the format, and the download starts on validation. Four versions ship with the platform: French and English, in PDF and Word.

Why the manual language is asked for

It is not inferred from the interface language. A staff member using the platform in French may need the English version for a technical or financial partner, and the other way round. The form offers the current language by default, without imposing it.

The Home tab

The Home tab is the entry point and a reminder of scope. It has four blocks.

- A banner with the two main entry points, the dashboard and the database.
- The real figures of the database: number of active indicators, categories, economies, observations, and the date of the last successful collection.
- Six cards detailing the features and the tab where they are found.
- Links to the institutions and to the providers' official sites.

The figures shown are queried from the database each time the tab opens. If they look low, the collection is incomplete: check the log in the Data collection tab.

The dashboard

The dashboard reads from top to bottom: pick a category, refine in the filter bar, read the chart and then the map.

Choosing a category

The first panel shows the fourteen categories, ordered to follow the logic of an economic outlook note: commodities first, then the real sector, public finance, the monetary sector, the external sector, exchange rates and interest rates.

Each tile states how many indicators it holds and how many have been collected. A category with nothing collected is flagged in orange.

The filter bar

Five settings, in this order, each narrowing the next.

6. Indicator. The list holds only indicators from the category. Those already collected come first; the others are marked as not collected. Up to six indicators may be selected.
7. Frequency. Only frequencies actually present in the database are offered. It adjusts to the first indicator chosen.
8. Period. The bounds match the indicator's effective coverage at the chosen frequency.
9. Countries. Only countries for which the indicator is populated appear, eight at most on one chart.
10. Apply filter. Nothing is redrawn before that click.

Why the cascades follow the first indicator

When several indicators are selected, the frequency, period and country list follow the first one. Combining them across all indicators would produce intersections that are often empty, and an empty filter is more confusing than a truncated secondary series. Check that your main indicator comes first in the selection.

Overlaying series

Two routes lead to the same result. Select several indicators at once in the list, then apply. Or build a selection, add it to the chart, compose another and add it in turn: that is the route for crossing indicators from different categories.

Each displayed series appears as a chip, removed with one click on the cross. The ceiling is six series.

Rebasing to 100 is sometimes imposed

When the displayed series do not share a unit, they are automatically rebased to 100 at their first observation. Overlaying a share of gross domestic product and a price in dollars per tonne on one axis would flatten one of the two beyond readability. The Base 100 box forces that treatment even when units agree, to compare relative movements rather than levels.

The four representations

Type	Recommended use	Avoid for
Lines	Movement of one or more series over time	Series with many gaps
Bars	Comparing levels over few periods	Long series, unreadable
Areas	Movement with emphasis on level	More than three overlaid series
Pie chart	Split across countries of an additive quantity	Percentages, indices, ranks

Table 4 – Chart types and recommended use

A pie chart sums the values

It keeps only the last displayed period, whose year appears in the title, and discards zero or negative values. Above all, it sums what it shows. For exports in dollars, that total means something. For shares of gross domestic product, indices or ranks, it means nothing: the platform still draws the chart but displays a warning. Do not circulate it in that case.

A series with gaps is drawn as a dashed line and never interpolated: joining two points several years apart with a solid line would suggest a movement that was not observed.

Projections

Three extension methods are offered, each with its interval. They apply to the first selected country and require at least five annual observations.

Method	Principle	Behaviour
Linear trend	Ordinary least squares on time	Robust, blind to regime breaks
Random walk with drift	Extends the mean of recent changes	The most neutral benchmark
Holt smoothing	Exponential smoothing with trend	Reacts better to recent turning points

Table 5 – Projection methods

What these projections are not

They are mechanical extensions of the observed series. They embed no policy assumption, no shock and no information outside the series itself. They must never be presented as a ministry forecast. For a macroeconomic framework, the tool is OPESc.

Exporting

The Image button produces a PNG file on a white background at print resolution, ready to paste into a note. The Data button produces a workbook holding exactly the displayed selection, with its sources sheet.

Map analysis

Below the chart, a world map shades countries by the indicator's value for a year chosen with the slider. A play button steps through the years automatically, showing a dynamic the chart cannot when countries are numerous.

The map follows the first displayed indicator. Overlaying several indicators on one colour scale would make no sense, as the units are not comparable.

Reading the scale

The scale is capped at the 2nd and 98th percentiles of the distribution. Without that precaution, a few extreme values would give every other country the same shade: on public debt, a handful of countries above 200 per cent of gross domestic product would flatten the whole reading. The tooltip always shows the real, uncapped value.

Regional aggregates are excluded from the map as from rankings. Countries in your selection are outlined more heavily.

The country profile

Clicking a country opens its panel on the right: flag, official language, region, income group, indicator value and world rank for the displayed year. The Ranking button exports the full ranking for that year.

Where the country details come from

The two-letter codes and official languages of 216 countries come from no statistical source: they are maintained by hand in a project file, editable without touching the code. A country missing from that table shows empty fields rather than breaking the map.

Chapter 6

The database

This tab gives access to the database without going through a chart. Filters cover category, indicators, countries, frequency and years.

The table shows the first thousand rows; the download covers the whole selection. Spreadsheet is the only download format offered, in two layouts.

Layout	Structure	Use
Long format	One row per observation	Statistical processing, import into analysis software
Cross table	One row per country and period, one column per indicator	Regression, table for a note

Table 6 – The two export layouts

Both workbooks carry a Sources sheet listing each indicator retained, its origin, its unit and the retrieval date.

Data collection

The platform updates itself by querying its providers' public interfaces. Every run is logged with its scope, trigger, status, the number of values added and revised, and the details of any errors.

Why a log

A collection can end without error and bring back nothing, for instance if a provider has renamed a code. Without a log, that silent failure would go unnoticed for months and analysis would rest on frozen series. Check the log after every update.

Triggering an update

From the Data collection tab, for one category or for the whole catalogue. A full collection means several hundred calls and takes thirty to forty-five minutes: proceed one category at a time.

The Refresh data button on the dashboard updates only the displayed indicators, which takes a few seconds.

Recommended rhythm

Macroeconomic data do not change from hour to hour.

Source	Publication rhythm	Recommended update
Pink Sheet, commodities	Monthly, early in the month	Weekly
World Development Indicators	Two to four revisions a year	Monthly
World Economic Outlook	April and October	Monthly
Atlas of Economic Complexity	Annual	Quarterly

Table 7 – Publication rhythm of the sources

Methodology

Period normalisation

Every observation is placed on the first day of the period it covers: 1 January for a year, the first day of the quarter, the first day of the month. This convention is what allows series of different frequencies to be overlaid on one chart.

Aggregating a monthly series

Commodity prices are collected monthly and also aggregated into annual averages; otherwise they would share no frequency with annual indicators and could not be compared.

The aggregation used is the arithmetic mean of the months in the year. A price is a period average: summing twelve monthly quotations would produce no interpretable quantity. For a flow, such as monthly exports, the sum would be the rule; the current catalogue holds none.

Rebasing to 100

Each series is divided by its first non-missing observation within the displayed period, then multiplied by one hundred. A series whose first value is zero or missing is dropped from the chart rather than producing infinite values that would flatten the other curves.

Projections

All three methods rely solely on the annual observations available for the chosen country.

The linear trend fits a straight line by ordinary least squares and extends it. The interval is built from the standard deviation of the residuals.

The random walk with drift takes the mean change over the last five periods and adds it to the last observed value, once per horizon step. Uncertainty grows with the square root of the horizon, reflecting the accumulation of successive errors.

Holt smoothing updates a level and a trend at each period, each weighted between the new observation and the previous extrapolation. It therefore reacts faster to recent turning points than the linear trend.

Map scale

The colour bounds are the 2nd and 98th percentiles of the value distribution for the displayed year, aggregates excluded. Values beyond take the extreme shade without stretching the scale.

Missing values

A missing value is never stored. The absence of a row means absence of data, never zero. Providers nonetheless return a row for every country-period pair, including where there is no data: on an indicator with sparse coverage, more than nine tenths of the volume would be empty rows.

As a result, a series with gaps is drawn as a dashed line with visible points, and never interpolated.

Limitations and points to watch

Country coding

Providers do not use the same coding. The country table keeps, for each economy, the reference identifier and those specific to each source. Without that mapping, joins would produce incomplete series with no error raised.

Revisions

Macroeconomic data are revised. A 2023 gross domestic product figure collected in January may differ from the same figure collected in June. The platform keeps the latest known value and the collection date, with no vintage history. A published note must therefore carry its retrieval date.

Economic complexity

The Economic Complexity Index is not measured but computed across all countries and products simultaneously. A revision to one large exporter's trade data mechanically shifts every other country's index. Values are therefore not comparable from one Atlas release to the next.

Furthermore, a year's trade data reach the Atlas only about two years later: the latest available year will always lag the rest of the dashboard by that much.

Commodity price units

They are read directly from the provider's workbook rather than copied. They may therefore differ from other publications: cocoa is quoted per kilogram in the Pink Sheet and per tonne in some sources. Always check the unit shown on the axis before quoting a level.

Fine frequencies

The schema provides for weekly, daily and intraday steps, but no catalogue source feeds them. This is not a limitation of the tool: a quarterly gross domestic product has no daily value. Those steps only make sense for market data, which come from other providers and are often paid.

Why almost everything is annual

The World Bank, which supplies most of the active indicators, publishes annual data only. The only monthly series in the catalogue are commodity prices. If the frequency filter offers nothing but Annual, that is not a fault: no sub-annual series has been collected.

Quick operating guide

Consulting an indicator

11. Open the Dashboard tab.
12. Choose the category in the first panel.
13. Select one or more indicators.
14. Check the frequency offered and adjust the period.
15. Choose the countries.
16. Click Apply filter.
17. Read the chart, then the map below.
18. Click a country on the map to open its profile.
19. Export as an image or a spreadsheet.

Comparing several indicators

20. Build a first selection and apply it.
21. Change category and build a second selection.
22. Click Add to chart.
23. Check the unit on the axis: if units differ, base 100 is imposed.
24. Remove a series with one click on the cross of its chip.

Updating the data

25. Open the Data collection tab.
26. Choose the scope, preferably one category.
27. Click Refresh and let the run finish.
28. Read the line added to the log, especially the errors column.
29. Return to the dashboard and check that the period has extended.

Frequently asked questions

The filter only offers annual frequency

That is the normal case for most indicators: the World Bank publishes annual data only. Only commodity prices exist monthly.

An indicator is marked as not collected

It is in the catalogue but has never been retrieved. Run a collection on its category from the Data collection tab.

The chart is empty although the indicator is collected

Widen the period, or check that the selected countries are populated for that indicator. Coverage varies a great deal: a poverty indicator may exist for only three years out of sixty in a given country.

The map stays grey for many countries

Those countries have no value for the displayed year. Move the slider to an earlier year: coverage is often better a few years back than for the most recent year.

Can a value be edited

No. The platform is read-only for the user. An erroneous value is the provider's responsibility and should be reported to them.

Do the projections commit the ministry

No. They are statistical extensions of the observed series, with no policy assumption. They must not be circulated as an institutional forecast.

A pie chart shows a warning

The series shown are not additive, for instance shares of gross domestic product. The pie total then means nothing. Choose a quantity in levels, or another chart type.

Appendix A

Indicator catalogue

The tables below list the 233 active indicators by category. The collection code is the one used with the provider: it must not be altered. Unless stated otherwise the frequency is annual; commodity prices are monthly and also aggregated into annual averages.

C01. Commodities

Appendix B

Frequency reference

The database schema recognises seven steps. Not all are fed.

Code	Label	Fed today
A	Annual	Yes, most of the catalogue
S	Half-yearly	No
T	Quarterly	No
M	Monthly	Yes, commodity prices
H	Weekly	No
J	Daily	No
I	Intraday	No

Table 22 – Recognised frequencies

Steps that are not fed are never offered in the filter. The day a source feeds them, they will appear with no interface change.

Glossary

Term	Definition
Aggregate	A grouping of countries published by the provider: the world, a region, an income group. Excluded from maps and rankings.
Base 100	Transformation rebasing each series to one hundred at its first observation, to compare relative movements.
Category	One of the fourteen thematic groupings of indicators.
Collection code	Identifier of the series with its provider. Must not be altered.
Collection	Running the connectors towards the providers, followed by writing to the database.
Connector	Component responsible for querying one provider and normalising its response.
Frequency	Time step of a series: annual, quarterly, monthly.
Collection log	Timestamped record of each run, with its status and errors.
Observation	One value, for an indicator, a country, a frequency and a period.
Projection	Statistical extension of the observed series, with no economic assumption.
Series	An indicator, a frequency and a set of countries, displayed together.
Series with gaps	A series with missing periods, drawn as a dashed line.
